

<b>Communicable disease</b>	Infectious diseases that can be passed from person to person. Caused by pathogens e.g. measles
<b>Non-communicable disease</b>	Cannot be transmitted from one person to another e.g. arthritis.
<b>Pathogen</b>	Microorganisms that enter the body and cause disease. Spread in water, air and direct contact.

**Topic B3- Infection and Response**

**Bacteria**  
 Reproduce rapidly.  
 Produce toxins to make you feel ill.  
 Damage your cells and tissues.

**Virus**  
 Lives and replicates within body cells. Once inside cells make copies and then the cell bursts releasing new viruses. It is difficult to kill viruses without damaging body cells.

Disease	Pathogen	How it is spread	Effect/symptoms	Prevention/control
<b>Salmonella</b>	Bacteria	Infected foods.	Fever, stomach cramps, vomiting and diarrhoea.	Vaccination of poultry .
<b>Gonorrhoea</b>	Bacteria	Sexual contact.	Pain when urinating, thick yellow or green discharge from the vagina or the penis.	Controlled by antibiotics. Spread prevented by using condoms.
<b>Measles</b>	Virus	Droplets from an infected person's sneeze or cough.	Red skin rash, fever. If complications occur measles can be fatal.	Vaccination.
<b>HIV</b>	Virus	Sexual contact or exchanging body fluids.	Flu-like symptoms. Leading to the virus attacking the immune system.	Antiretroviral drugs
<b>Tobacco Mosaic Virus</b>	Virus	Direct contact.	Discoloration of leaves leading to a mosaic pattern. The leaves have less chlorophyll to absorb sunlight which reduces photosynthesis.	
<b>Rose Black Spot</b>	Fungus	Spores carried by water or wind.	Purple and black spots on the leaves. Leaves then turn yellow and fall off, reducing photosynthesis.	Use fungicides, strip off the affected leaves and destroy.
<b>Malaria</b>	Protist	Mosquitoes are the vectors which spread malaria.	Repeated episodes of fever, can be fatal.	Spread can be reduced by preventing mosquitoes from breeding and using mosquito nets.

Non-specific body defences	
<b>The skin</b>	Physical barrier which stops pathogens from getting in.
<b>Nose hairs</b>	They trap particles that could contain pathogens.
<b>Mucus</b>	The trachea and bronchi release mucus to trap pathogens.
<b>Cilia</b>	The trachea and bronchi are lined with cilia which move the mucus up to the back of the throat where it can be swallowed.
<b>Stomach acid</b>	The stomach makes hydrochloric acid to destroy pathogens.

<b>Antibodies</b>	Produced by white blood cells called lymphocytes. These bind to pathogens and destroy them or stick them together.
<b>Antitoxins</b>	Produced by white blood cells called lymphocytes. Antitoxins neutralise toxins.
<b>Antibiotics</b>	Antibiotics kill bacteria. Specific antibiotics kill specific bacteria. Some bacteria have become resistant to certain antibiotics.
<b>Painkillers</b>	No effect on the pathogens but do reduce the symptoms of the illness. Paracetamol and aspirin are examples of painkillers.
<b>Phagocytosis</b>	Some white blood cells called phagocytes engulf pathogens.
<b>Penicillin</b>	An antibiotic produced by Penicillium. Kills bacteria.

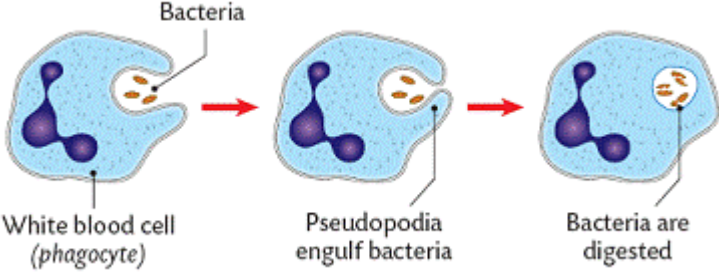

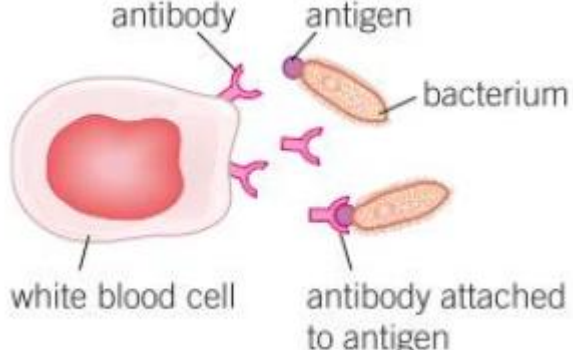

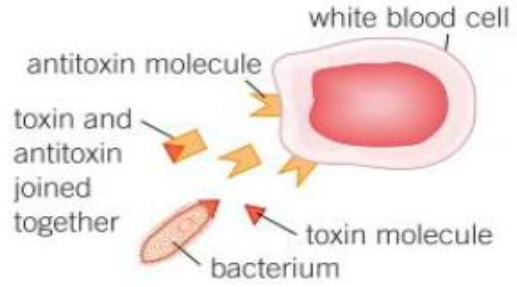

Vaccinations
1-Dead or inactive pathogen is injected into the patient.
2-The antigens on the surface of the pathogen cause white blood cells to produce a specific antibody to attack the pathogen.
3-If the person is infected again with the same pathogen, white blood cells quickly produce the specific antibodies.
4-The antibodies quickly destroy the pathogen so that the person does not get ill.

Drug testing		
Trial stage	Procedure	Purpose
<b>Preclinical testing</b>	Drugs are first tested on human cells and tissues. Followed by testing on animals.	Test for efficacy, toxicity and dosage.
<b>Clinical testing</b>	Tested on human volunteers. Firstly on healthy volunteers.	To make sure that the drug does not have any harmful side effects.
	Secondly- if results are good it is tested on people who have the illness. Small sample group.	To find the optimum dosage and to see how the illness response to the drug.
	Next patients are divided into two groups. Group 1 is given the new drug, group 2 is given a placebo. The clinical trial is 'blind' or even 'double blind'.	To see if the drug makes a real difference. To avoid bias.
	The results of these tests are not published until they have been through a peer review.	To avoid bias and false claims.

Pros and cons of vaccinations
<b>Pro-</b> vaccines help to control lots of communicable diseases.
<b>Pro-</b> Epidemics can be prevented if lots of people are vaccinated.
<b>Con-</b> Vaccines don't always work
<b>Con-</b> Sometimes people have bad reactions to vaccines.

<b>Efficacy</b>	Whether a drug works and has the desired effect.	<b>Dosage</b>	The concentration of the drug that works the best and how often it should be taken by the patient.
<b>Toxicity</b>	How harmful the drug is and whether it has any side effects.	<b>Placebo</b>	A drug with no active ingredients, designed to mimic a real drug. Used to test if the effects of a drug on a patient are just psychological.
<b>Blind test</b>	The patient doesn't know if they are taking the new drug or a placebo.	<b>Double blind test</b>	Neither the patient nor the doctor know if they are taking the new drug or the placebo.

White blood cells		
<b>Phagocytosis</b>	The white blood cells engulf the pathogen.	 <p>The diagram illustrates the process of phagocytosis in three stages. In the first stage, a white blood cell (phagocyte) is shown with several small, yellow, oval-shaped bacteria nearby. In the second stage, the white blood cell extends its membrane as pseudopodia to surround and engulf the bacteria. In the third stage, the bacteria are fully inside the white blood cell, and they are shown being digested.</p>
<b>Produce antibodies</b>	Invading pathogens have molecules called antigens on their surface which white blood cells do not recognise. Certain white blood cells called lymphocytes produce specific antibodies. These antibodies lock on to the pathogens antigens. The antibodies ensure that the pathogens can be found and destroyed by other white blood cells.	 <p>The diagram shows a white blood cell on the left, which is producing antibodies (represented as Y-shaped molecules). On the right, there is a bacterium with antigens (represented as small purple structures) on its surface. The antibodies are shown attaching to these antigens, forming an 'antibody attached to antigen' complex.</p>
<b>Produce antitoxins</b>	Certain white blood cells make antitoxins to neutralise the toxins made by pathogens.	 <p>The diagram shows a white blood cell on the right, which is producing antitoxin molecules (represented as yellow arrowheads). On the left, there is a bacterium releasing toxin molecules (represented as red arrowheads). The antitoxin molecules are shown binding to the toxin molecules, forming a 'toxin and antitoxin joined together' complex, which neutralizes the toxin.</p>
